摘要: 海岸带耐盐植物是一个生态和经济价值独特的庞杂类群, 人们对其DNA条形码特性的了解甚少。本文对我国从辽宁到海南10个沿海省(市)大陆及岛屿海岸带耐盐植物广泛采样, 从采集获得的样品中筛选出53科97属116个物种共562个样品进行DNA条形码研究。对3个叶绿体片段(*matK*、*rbcL*、*trnH-psbA*)和1个核基因片段(ITS)进行了扩增和测序, 统计各个片段的引物通用性和序列获得率, 并检验了物种识别率。从序列获得率来看, *matK*和*trnH-psbA*片段表现最好, ITS较差, ITS和*matK*的引物通用性比其他2个片段差。序列相似性分析表明, 单个片段ITS物种识别率最高(73.36%), 其次为*matK* (64.03%)和*trnH-psbA* (61.21%), *rbcL*的物种识别率最低, 仅为46.41%。系统发育树分析显示*matK*的物种识别率最高(82.3%), 依据*trnH-psbA*片段难以获得可靠的系统发育树。多维度非度量分析(non-metric multidimensional scaling, NMDS)表明在进行海岸带区域性植物的DNA条形码研究时, 叶绿体片段和核基因片段均应该考虑。综合上述研究结果, 推荐联合片段ITS + *matK*作为中国海岸带耐盐植物DNA条形码。本文为海岸带耐盐植物研究提供了总计1,939条DNA条形码基础数据, 为构建耐盐植物DNA条形码数据库奠定了基础。

Abstract: Halo-tolerant plants compose a huge group of plants with unique ecological and economical value. Little is known about their DNA barcoding speciality. In this study, 562 samples of coastal halo-tolerant plants (including 53 families, 97 genera and 116 species) were collected from 10 coastal provinces, ranging from Liaoning to Hainan. Three chloroplast DNA markers (*matK*, *rbcL* and *trnH-psbA*) and one nuclear DNA marker (ITS) were amplified and sequenced. Primer universality and sequence availability of each locus were examined and species resolution rates were tested. When considering sequence availability, *matK* and *trnH-psbA* were among the best. But the primer universality of ITS was marginally worse than expected. The all-to-all BLASTn searches indicated that the species resolution rate of ITS was the highest (73.36%), followed by those of *matK* (64.03%), *trnH-psbA* (61.21%) and *rbcL* (46.41%). Phylogenetic trees (NJ trees) indicated that the species resolution rate of *matK* was the highest (82.3%), but no reliable NJ tree based on *trnH-psbA* could be acquired because of unequal sequence length. NMDS and PCoA results demonstrated that both chloroplast DNA markers and nuclear DNA markers should be considered when conducting coastal plant DNA barcoding studies. Based on the above results, we suggest that the combination of ITS + *matK*

should be regarded as the barcode for halo-tolerant plants in Chinese coastal regions. In total, the 1939 newly acquired sequences in this study lay the foundation for a DNA barcode database of coastal halo-tolerant plants.

Key words: DNA barcoding; coastal region; halo-tolerant plants; species resolution rate; ITS; *matK*

耐盐植物包括盐生植物(赵可夫和李法曾, 1999; 林鹏, 2006)和一些能在盐渍生境正常生长的非盐生植物, 如在海岸高潮带附近盐渍化生境中的白茅(*Imperata cylindrica*)、芦苇(*Phragmites australis*)及海杧果(*Cerbera manghas*)等(王文卿, 2013)。据统计, 我国海岸带耐盐植物约有517种(陈兴龙等, 1999)。以耐盐植物为主体形成的海岸带近海湿地生态系统, 是全球单位面积生态服务功能最高的生态系统之一。它们极高的初级生产力和营养循环能力对海岸水体的物理、化学和生物环境带来了深远的影响(Short et al, 2007; Gedan et al, 2011; Sandilyan & Kathiresan, 2012)。然而沿海地区众多环境问题的出现, 造成海岸湿地面积衰减迅速(Waycott et al, 2009), 植物物种多样性也受到显著影响(Molnar et al, 2008; Seebens et al, 2013), 因此对耐盐植物的生物多样性保护工作十分迫切。

DNA条形码技术已经有十多年的发展历史(Hebert et al, 2003; CBOL Plant Working Group, 2009; China Plant BOL Group, 2011), 但比较、推荐合适的DNA条形码片段依然有大量的工作有待完成(Kress et al, 2010; Hollingsworth, 2011; Li et al, 2012; Braukmann et al, 2017)。早期的研究工作多关注特定分类单元的最适DNA条形码筛选, 在特定分类单元或不同谱系中, 物种识别率的差异主要归因于不同类群的进化历史(Ebihara et al, 2010; Hollingsworth et al, 2011)。将DNA条形码技术引入群落生态学和区系地理学中, 是系统发育生物学、生态学与条形码技术的交叉融合, 已成为近年来新的研究热点(Kress et al, 2015; 李德铢和曾春霞, 2015; Pei et al, 2017)。对于区域性植物的DNA条形码研究, 目前较多地集中在热带森林及亚热带森林(Gonzalez et al, 2009; Kress et al, 2009; Parmentier et al, 2013; Liu et al, 2015), 与此同时, 一些重要区域的植物DNA条形码库逐渐形成和充实(Burgess et al, 2011; Costion et al, 2011; De Vere et al, 2012; Parmentier et al, 2013)。由此, DNA条形码不仅可作为一种快速识别物种的方法, 也为快速评价和保护特

定区域的生物多样性提供了工具。

海岸带耐盐植物中有许多类群形态学鉴定难度较大, 如米草属(*Spartina*) (Baumel et al, 2001)、藜属(*Chenopodium*) (Bera et al, 1993; Rana et al, 2012)、碱蓬属(*Suaeda*) (Chu et al, 2003)、川蔓藻属(*Ruppia*) (Ito et al, 2010; Triest & Sierens, 2010)等。但仅有少数滨海耐盐植物类群有DNA条形码的研究报道(Schwarzbach & Ricklefs, 2000; Bafeel et al, 2012; Lucas et al, 2012; Munir et al, 2015)。同时由于其生境位于海陆交界处, 交通不便, 进行海洋生物(如海草、红树植物等)条形码研究时, 陆生耐盐植物经常被忽略(Trivedi et al, 2016); 而进行陆生植物相关研究时, 滨海耐盐植物同样难以得到重视(Bafeel et al, 2012; Lucas et al, 2012; Munir et al, 2015)。因此, 本文重点关注我国滨海海洋湿地生态系统中耐盐植物DNA条形码的获取及其物种识别率分析比较, 为建立海岸带生态系统中耐盐植物的DNA条形码数据库奠定基础。

1 方法

1.1 样品收集

本研究样品采集地涵盖辽宁到海南的11个沿海省市24个县市, 对海岸带耐盐植物进行了广泛的样品采集, 每个样品对应采集凭证标本2份及分子材料1份。广布物种每个样品的采样点间距大于100 km, 狹域分布种样品的采样点间距不小于20 km, 共获得2,300余号标本。选取含5个样品以上、分布点代表性好的物种共计116种562个样品进行实验。凭证标本存放于华东师范大学生命科学学院植物标本馆(HSNU); 采集记录详见附录1。

1.2 DNA提取、扩增及测序

根据生命条形码联盟(Consortium for the Barcode of Life, CBOL)推荐及前人进行大范围区域性植物DNA条形码的研究数据(CBOL Plant Working Group, 2009), 本研究选取4个候选片段, 包括1个核基因片段(ITS)及3个叶绿体基因片段(*matK*、*rbcL*及*trnH-psbA*)。采用CTAB法提取总DNA并进行扩增, 4

个片段的扩增体系见附录2。DNA片段扩增后的测序工作委托上海华津(Huagene)公司完成, 测序引物与PCR引物相同。由于 $matK$ 引物通用性低, 对禾本科所有物种、马鞭草科的单叶蔓荆(*Vitex rotundifolia*)、大戟科的海滨大戟(*Euphorbia atoto*)进行PCR和测序时使用引物 $matK$ -390F/ $matK$ -1326R, 其他物种则使用 $matK$ 3F-KIM/ $matK$ IR-KI (Cuénoud et al, 2002)。引物与PCR条件详情见附录3。

1.3 数据处理

1.3.1 物种识别率的获得

使用Seqman(DNASTAR package, Burland, 2000)软件对测序公司返回的序列的波峰进行检查, 拼接结果以.seq格式输出保存。使用Mega 5.0 (Tamura et al, 2011)的MUSCLE功能对所得序列进行比对, 最终输出.fas格式。使用软件BLASTN v2 (Tatusova & Madden, 1999)进行all-to-all BLASTN searches (Altschul et al, 1990)。这种分析方法需要建立本地数据库, 即已有的全部序列信息的本地数据库, blast结果是返回查询序列与数据库序列比对的得分。由于海岸带耐盐植物物种分布区跨度大、种内变异较大, 且单种属及寡种属占绝大多数, 种间差异大且种内样品间的序列一致性较低, 因此, 当查询序列与数据库中同种不同样品序列比对时的一致性比例达98%以上(且为最高值), 该查询序列所属的物种的全部样品序列都能达到此标准, 排除不同物种间样品比对也获得同样高的序列一致性比例的情形, 可认为该物种鉴定成功。手动统计所有样品比对结果, 得出物种识别率(Liu et al, 2015)。联合片段的比对是在单个片段基础上累加。系统发育方法neighbour-joining (NJ)分析时使用MEGA上neighbour-joining选项, 选择parametric-distance, 进行1,000次迭代的聚类分析, 所有样品聚为一支单系(自展值>50%), 认为该物种鉴定成功。统计单个片段和联合片段的物种识别率。

1.3.2 NMDS分析

使用多维度非度量(non-metric multidimensional scaling, NMDS) (Kruskal, 1964)方法对物种识别结果[0,1]矩阵进行排序分析, 该分析在R语言软件包中的VEGAN软件(R Core Team, 2012)中完成。NMDS分析结果优劣依赖应力系数值(stress)的大小(Khalaf & Kochzius, 2002)。选用Bray-Curtis距离, 因

为其在大范围和小范围的坐标轴上都具有稳健性(Newmaster et al, 2008; Liu et al, 2015)。NMDS运算的步骤如下: (1)将物种识别率处理为[0,1]矩阵, 鉴定成功为1, 鉴定失败为0, 最后储存.CVS格式的[0,1]矩阵; (2)打开R语言软件包, 调出VEGAN软件, 将[0,1]矩阵转换为Bray-Curtis距离; (3)使用mono-MDS函数进行运算、排序; (4)使用plot绘制图表。

2 结果

2.1 引物通用性及序列获得率

本实验共获得53科97属116个物种562个样品的1,939条序列数据。使用引物18sdir/ITS4 (White et al, 1990)对ITS进行扩增, 序列获得率略低(85.59%) (表1)。 $matK$ 3F-KIM/ $matK$ IR-KIM这对引物对 $matK$ 进行扩增时, 在藜科等效果很好, 但在禾本科扩增结果极差; 引物更换为 $matK$ -390F/ $matK$ -1326R, 禾本科测序结果较为理想, 所有物种均获得可靠序列。 $rbcL$ 的序列获得率为83.04%, 使用引物 $rbcL$ a-f/ $rbcL$ a-r进行扩增和测序时, 有5属5种每个样品均未获得序列信息, 相较于Kress等(2009)推荐的引物稍差。总体上, 从序列获得率来看, $matK$ 和 $trnH-psbA$ 片段表现最好, ITS和 $rbcL$ 相对较差, 但ITS和 $matK$ 均存在引物通用性的问题。

表1 序列获得率及片段长度

Table 1 Summary of the sequencing success rate and length of candidate barcoding fragments

片段名称 Locus	获得序列数 Species resolution	序列获得率 Sequence availability rate	测序成功物种数 Species successfully sequenced	片段长度 Fragment length (bp)
ITS	481	85.59%	106	304–632
$matK$	502	89.32%	116	611–721
$rbcL$	465	83.04%	109	371–650
$trnH-psbA$	491	87.36%	116	142–907

2.2 候选片段的物种识别率

2.2.1 序列相似性分析

使用序列相似性方法获得每个样品的BLASTN结果, 562个样品全部纳入分析, 其中由于测序原因, 一些物种仅有1个样品测序成功(ITS有4个物种, $matK$ 有1个物种, $rbcL$ 有6个物种, $trnH-psbA$ 有2个物种)。如序列矩阵中1个物种只包含1个样品(均由扩增或测序失败造成), 表明相应片段的个体间

差异大,为避免高估物种识别率,该物种处理为鉴定失败。将各个片段及联合片段的物种识别率绘制成柱状图,结果显示:单个片段ITS表现最好为73.36%,*matK*物种识别率为64.03%;*rbcL*、*trnH-psbA*在单个片段中表现一般,分别为46.49%、61.21%。联合片段中ITS+*matK*+*trnH-psbA*结果高达84.76%,ITS+*matK*两者联合结果也能达到83.02%(图1)。

本研究中属内物种数目多于1的属共15个,其中马唐属(*Digitaria*)、藜属各包含4个物种,其他均

为2~3个物种。统计这15个属的物种识别率(图2),结果显示:ITS为51.52%,是所有4个片段中最好的;片段联合分析,物种识别率最高的是ITS+*matK*+*trnH-psbA*(65.71%),其次是ITS+*matK*+*rbcL*(62.56%)和ITS+*matK*(62.50%)(图2)。显然,与图1数据相比,当属内物种数目增多时,片段的鉴定能力明显下降。

2.2.2 系统发育分析

基于ITS、*matK*和*rbcL*三个片段的全部样品构建系统发育树(NJ树略),统计物种识别率(图3),种

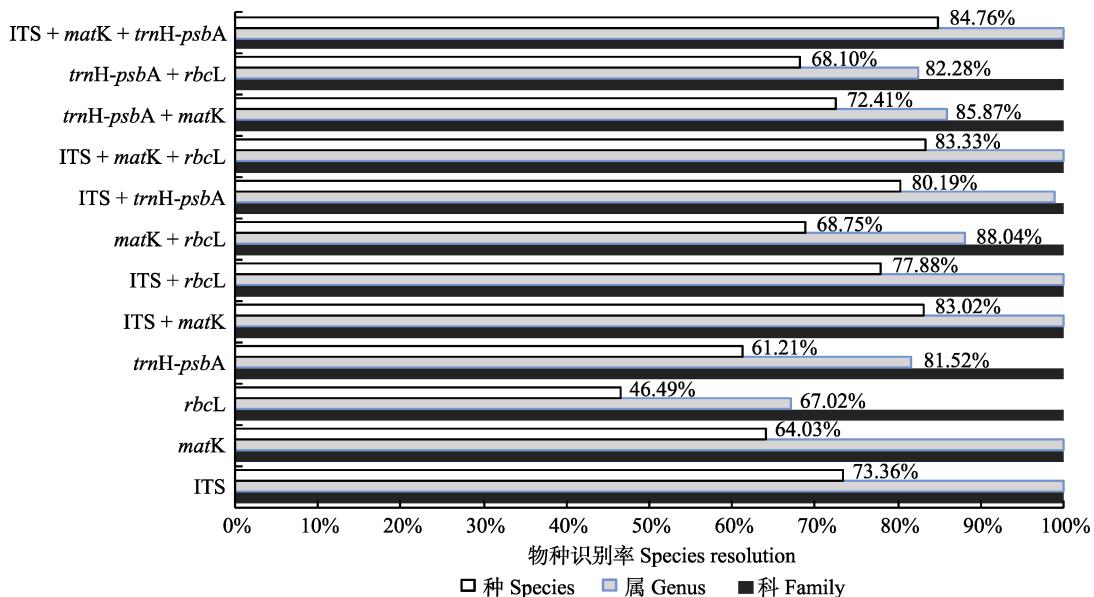

图1 序列相似性方法的物种识别率统计

Fig. 1 Species resolution rate from all to all BLASTn searches

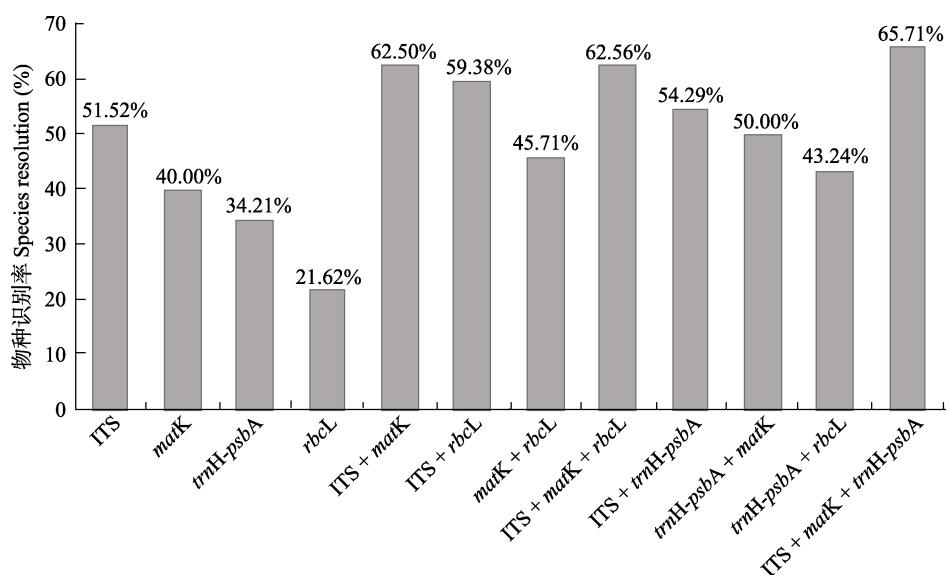

图2 属内物种数目多于1的15个属的物种识别率统计

Fig. 2 Species resolution rate of 15 genera which contain more than one species

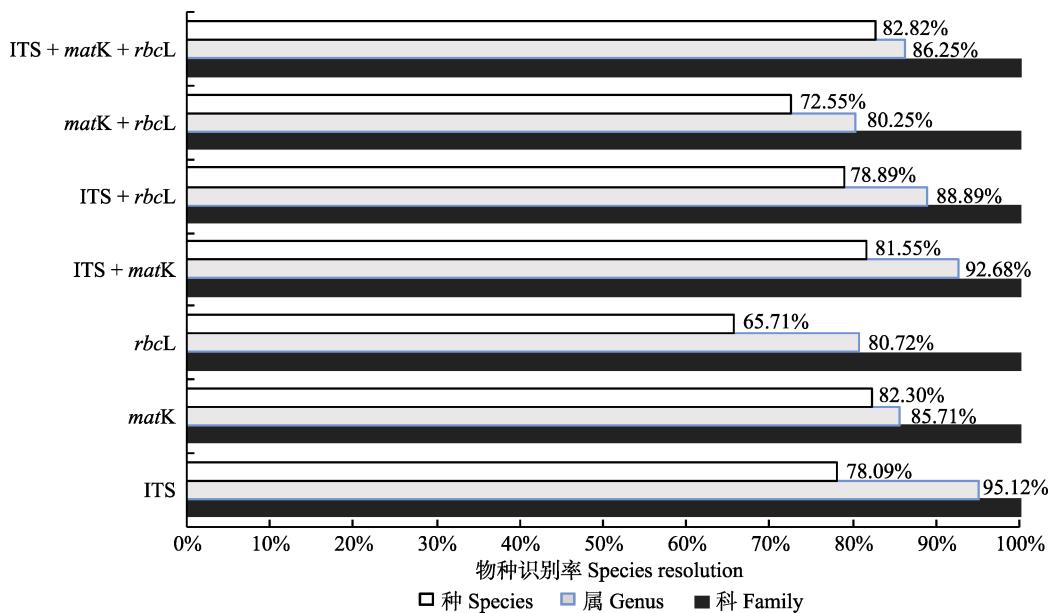

图3 系统发育方法的物种识别率统计

Fig. 3 Species resolution rate based on the phylogenetic method

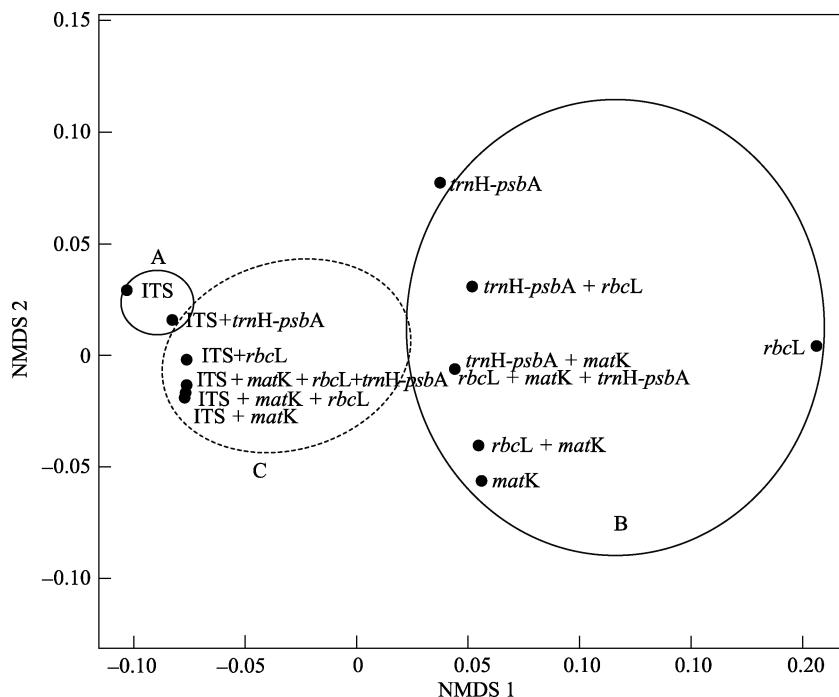

图4 候选DNA条形码片段的NMDS分析(Stress值: 0.011)

Fig. 4 Multivariate analysis of non-metric multidimensional scaling for the four barcode markers NMDS. Stress value: 0.011.

内所有样品聚为一支，即认为物种鉴定成功。NJ树的结果显示 *matK* 表现最好(82.30%)，其次是 *ITS* (78.09%)。在科/属水平的物种识别率趋势与物种水平基本一致，在属水平显示单个片段 *ITS* 效果最好(为95.12%) (图3)。不管是BLASTn结果还是NJ树结果，*rbcL* 的属、种识别率表现都是最差(图1, 图3)。

两片段 *ITS + matK* 联合及三片段 *ITS + matK + rbcL* 联合的物种水平识别率大体一致，约为82–83% (图3)。由于 *trnH-psbA* 片段长度不一致，比对相当困难，即使分科比对之后，将所有科的样品放在同一.fas 文件中，依然联合失败，因此未对其进行系统发育分析。

对比两种分析方法发现：单个片段表现最好的片段是ITS (73.36%) (图1)或matK (82.30%) (图3)，而最差的均是 $rbcL$ (46.49%、65.71%)。联合片段的结果中，BLASTn方法最好的是ITS + matK + $trnH-psbA$ (为84.76%)，NJ树的结果是ITS + matK + $rbcL$ (为82.82%)。虽然ITS + matK两者联合的结果稍低，但也能分别达到83.02% (图1)和81.55% (图3)。由于 $trnH-psbA$ 片段长度不一致，该片段未能包括在系统发育分析方法中。

2.3 核基因与叶绿体基因片段物种识别差异性分析

将基于BLASTn的物种识别率转换成Bray-Curtis矩阵，并用R语言软件包中的vegan软件进行NMDS运算。迭代20次，stress值就能趋于稳定达到0.011，说明排序结果十分可靠。图4中点的相互靠近代表相关片段间的物种识别差异性较小(相距越远代表差异性越大)。结果显示：叶绿体基因与核基因的物种识别在NMDS排序图中存在明显的A、B两个区域，表明这两类片段的物种识别差异性较大；而当核基因片段ITS与叶绿体片段联合时，排序位置(C区)处于A和B之间，表明这两类片段在物种识别中均发挥了作用(图4)。C区偏向靠近A区，则表明核基因片段ITS具有更强的物种识别能力，与前文进行物种识别率的运算时显示单个ITS的结果最好(图1)、叶绿体与ITS联合片段的物种识别率显著提高(图1)的结果一致。

3 讨论

3.1 ITS、matK、 $rbcL$ 和 $trnH-psbA$ 4个片段扩增及序列获得率比较

本文探讨了核基因片段ITS和叶绿体片段matK、 $rbcL$ 及 $trnH-psbA$ 作为条形码的潜在价值。使用1对引物可以扩增出所有耐盐植物的ITS，但在测序时碰到一定的困难，芦竹属(*Arundo*)、大拂子茅(*Calamagrostis macrolepis*)、海刀豆(*Canavalia rosea*)、披碱草属(*Elymus*)等仍有80个样品测序未成功，使用引物ITS3/ITS4 (White et al, 1990)对ITS2扩增及测序，依然没有得到这些属的正确序列，序列获得率只有85.59%。导致测序失败的原因可能是由于ITS具有poly结构、异源多倍体的影响等，在很多研究中都有与本文相似的情况(Chase et al, 2005; Kress et al, 2005; Newmaster et al, 2006; Liu et al,

2016)，这是它作为优秀的条形码存在的最大问题。 $matK$ 基因片段全长为1,500 bp左右，引物通用性不高和单核苷酸重复序列一直是其在DNA条形码应用中的重大障碍(Coston et al, 2011; Yu et al, 2011; Parmentier et al, 2013)，通常利用全长的前半段进行系统发育和条形码分析(Sugita et al, 1985; Steane 2005; Barthet & Hilu, 2007; Yu et al, 2011)。本研究使用了2对通用引物才完成所有类群的扩增，并得到最好的序列获得率89.32% (表1)。 $rbcL$ 的序列获得率仅为83.04%，仍有共计97个样品未获得 $rbcL$ 序列信息，这应该是引物选择上的问题，已有研究表明这对引物不是扩增 $rbcL$ 序列的最佳引物(Kress et al, 2009)。如果换用最佳引物，预计序列获得率将得到一定的提升。尽管叶绿体 $trnH-psbA$ 片段使用1对引物扩增及测序在4个片段中表现比较优秀(表1)，但已有报道表明该片段存在长度不一致的严重问题(Chase et al, 2007)。本研究亦发现其长度变化极大：在碱蓬(*Suaeda glauca*)的长度仅有250 bp，在盐地碱蓬(*S. salsa*)的长度为400 bp，而在禾本科中长度则达750 bp。片段长度差别过大及插入/缺失过多导致比对联合无法进行，因此不适宜用于系统发育分析(Hamilton et al, 2003; Yamashiro et al, 2004; Newmaster et al, 2006)。

由此可见，从各片段的引物通用性及序列获得率综合分析，我们认为针对滨海耐盐植物而言，没有哪一个片段完美无缺，在条形码的实际应用中更重要的是参考物种识别率进行择优。

3.2 相关DNA片段的物种识别率及最优条形码推荐

前人研究发现ITS进化速率比叶绿体片段快3-4倍，因此在很多系统分类学研究中将ITS作为目标片段之一(Chase et al, 2007)。本研究的序列相似性分析发现在种水平，单个片段ITS物种识别率表现最好(73.36%) (图1)，而NJ树分析结果也达到78.09% (图3)。ITS不仅在一些大属如梅花草属(*Parnassia*)、无花果属(*Ficus*)、庭菖蒲属(*Sisyrinchium*)、报春花属(*Primula*)等的研究中相比于其他单个片段表现较好(Li et al, 2012; Yang et al, 2012; Alves et al, 2014; Yan et al, 2015)，在给定的地理区域进行样品收集和植物DNA条形码评价时，也发现ITS(ITS2)的物种识别率表现最好(Liu et al, 2015)。同时有报道根据物种识别率推荐ITS作为种子植物

的DNA条形码(China Plant BOL Group, 2011)。

*matK*是叶绿体片段中表现最出色的片段之一, 在核酸水平和氨基酸水平的替换率与*rbcL*相比分别高3倍和6倍, 变异位点也多于*rbcL* (Olmstead & Palmer, 1994; Barthet & Hilu, 2007)。本研究中NJ方法中*matK*物种识别率表现最好, 为82.3% (图3), 在BLASTn方法中仅次于ITS (图1), 在属水平的识别率和属中物种数目多于1时物种水平的识别率都较其他叶绿体片段优秀(图1、2)。本研究经综合比较, 认为*matK*是值得推荐为海岸带生态系统的耐盐植物DNA条形码之一。

前人研究曾提出以*matK* + *rbcL*作为陆生植物核心条形码片段(CBOL Plant Working Group, 2009), 而越来越多研究发现尽管*rbcL*的扩增和测序都比较容易, 但其缺乏足够多的变异位点(China Plant BOL Group, 2011)。我们也发现滨海耐盐植物尽管在科水平*rbcL*的识别率能达到100%, 但在属及物种水平上的识别率最低(图1、2、3), 没有足够的变异位点将大量类群区分开。因此推测在进行广泛的区域性高等植物DNA条形码研究时, *rbcL*并不适合。

*trnH-psbA*作为进化速率最快的片段之一, 在某些属如龙胆属(*Gentiana*)、碱蓬属等属内的变异幅度比较大(Chase et al, 2007; Dong et al, 2012; Liu et al, 2016); 在禾本科、天门冬科、唇形科等科的一些物种的*trnH-psbA*片段中有*rps19*插入(Pang et al, 2012)。插入和缺失导致片段长度差异较大, 在植物类群繁多的区域DNA条形码研究中无法运用系统发育方法进行分析(Hamilton et al, 2003; Yamashiro et al, 2004; Newmaster et al, 2006)。即使进行序列相似性分析, *trnH-psbA*的物种识别率也较低(61.21%) (图2)。

在进行区域性DNA条形码的研究中, 前人主要研究*matK*、*rbcL*及*trnH-psbA*三个叶绿体片段。Kress等(2009)对Panama区域内296个木本物种进行研究, 发现叶绿体片段*matK* + *rbcL*的物种识别率高达98%, 但这一高识别率是源于大量科、属只包含1个物种; Gonzalez等(2009)的研究中*matK* + *rbcL*在木本植物只有61%的分辨率(Gonzalez et al, 2009); 在Liu等(2015)对鼎湖山国家级自然保护区的531种木本植物研究中, *matK* + *rbcL*也仅有66.83%的物种识别率。本研究中对海岸带耐盐植物进行广泛取样, 研究结果表明*matK*的序列相似性分析得到的物种

识别率为64.03%, 与前人进行区域植物DNA条形码的研究结果大体一致(Gonzalez et al, 2009; Liu et al, 2015)。而相对于叶绿体基因, 我们发现核基因ITS与叶绿体基因对物种的识别存在差异性, ITS与叶绿体片段联合后能将物种识别率提高到83.02% (图1、4), 所以在进行海岸耐盐植物DNA条形码研究时, 核基因与叶绿体基因都应该考虑。综合研究结果, 本文推荐以ITS + *matK*作为中国海岸带耐盐植物的DNA条形码。

但这2个片段在亲缘关系十分靠近的类群中作为DNA条形码表现并不完美(Chase et al, 2005; De Vere et al, 2015)。在已有报道中表明二型马唐(*Digitaria heterantha*)、马唐(*D. sanguinalis*)和升马唐(*D. ciliaris*)之间亲缘关系非常近(Vega et al, 2009; Adoukonou-Sagbadja et al, 2010), 分享共同祖先。本研究表明ITS + *matK*无法提供足够的变异位点将马唐属的4个物种分开。所以对于大属来说, 如果该属存在亲缘关系比较近的物种, DNA条形码的分辨率会下降(Ebihara et al, 2010; Liu et al, 2016), 需要发现新思路加以解决。

3.3 关于中国海岸带耐盐植物DNA条形码数据库

本研究针对中国海岸带生态系统中盐沼植物和非盐生耐盐植物获得了1,939个条形码序列信息, 源自116个物种562个样品, 占中国海岸带中耐盐植物的22.43%。由于中国海岸带面积宽广、耐盐植物数量众多、测序分析的工作量巨大, 后续研究还需要补充更多耐盐植物物种, 并且补充整合海草及红树植物数据, 构建一个完整、高覆盖度的DNA条形码数据库。

致谢:感谢华东师范大学刘文亮博士、研究生张振、张丽芳和本科生杨主爱对本文样品采集提供的帮助。
